来源 | <https://zhuanlan.zhihu.com/p/104019160>

极市导读

本文是PyTorch常用代码段合集，涵盖基本配置、张量处理、模型定义与操作、数据处理、模型训练与测试等5个方面，还给出了多个值得注意的Tips，内容非常全面。

PyTorch最好的资料是官方文档。本文是PyTorch常用代码段，在参考资料[1](张皓：PyTorch Cookbook)的基础上做了一些修补，方便使用时查阅。

1. 基本配置

导入包和版本查询

```
1 import torch
2 import torch.nn as nn
3 import torchvision
4 print(torch.__version__)
5 print(torch.version.cuda)
6 print(torch.backends.cudnn.version())
7 print(torch.cuda.get_device_name(0))
```

可复现性

在硬件设备（CPU、GPU）不同时，完全的可复现性无法保证，即使随机种子相同。但是，在同一个设备上，应该保证可复现性。具体做法是，在程序开始的时候固定torch的随机种子，同时也把numpy的随机种子固定。

```
1 np.random.seed(0)
2 torch.manual_seed(0)
3 torch.cuda.manual_seed_all(0)
4
5 torch.backends.cudnn.deterministic = True
6 torch.backends.cudnn.benchmark = False
```

显卡设置

如果只需要一张显卡

```
1 # Device configuration
2 device = torch.device('cuda' if torch.cuda.is_available() else 'cpu')
```

如果需要指定多张显卡，比如0，1号显卡。

```
1 import os
2 os.environ['CUDA_VISIBLE_DEVICES'] = '0,1'
```

也可以在命令行运行代码时设置显卡：

```
1 CUDA_VISIBLE_DEVICES=0,1 python train.py
```

清除显存

```
1 torch.cuda.empty_cache()
```

也可以使用在命令行重置GPU的指令

```
1 nvidia-smi --gpu-reset -i [gpu_id]
```

2. 张量(Tensor)处理

张量的数据类型

PyTorch有9种CPU张量类型和9种GPU张量类型。

Data type	dtype	CPU tensor	GPU tensor
32-bit floating point	<code>torch.float32</code> or <code>torch.float</code>	<code>torch.FloatTensor</code>	<code>torch.cuda.FloatTensor</code>
64-bit floating point	<code>torch.float64</code> or <code>torch.double</code>	<code>torch.DoubleTensor</code>	<code>torch.cuda.DoubleTensor</code>
16-bit floating point	<code>torch.float16</code> or <code>torch.half</code>	<code>torch.HalfTensor</code>	<code>torch.cuda.HalfTensor</code>
8-bit integer (unsigned)	<code>torch.uint8</code>	<code>torch.ByteTensor</code>	<code>torch.cuda.ByteTensor</code>
8-bit integer (signed)	<code>torch.int8</code>	<code>torch.CharTensor</code>	<code>torch.cuda.CharTensor</code>
16-bit integer (signed)	<code>torch.int16</code> or <code>torch.short</code>	<code>torch.ShortTensor</code>	<code>torch.cuda.ShortTensor</code>
32-bit integer (signed)	<code>torch.int32</code> or <code>torch.int</code>	<code>torch.IntTensor</code>	<code>torch.cuda.IntTensor</code>
64-bit integer (signed)	<code>torch.int64</code> or <code>torch.long</code>	<code>torch.LongTensor</code>	<code>torch.cuda.LongTensor</code>
Boolean	<code>torch.bool</code>	<code>torch.BoolTensor</code>	<code>torch.cuda.BoolTensor</code>

张量基本信息

```
1 tensor = torch.randn(3,4,5)
2 print(tensor.type()) # 数据类型
3 print(tensor.size()) # 张量的shape，是个元组
4 print(tensor.dim())  # 维度的数量
```

命名张量

张量命名是一个非常有用的方法，这样可以方便地使用维度的名字来做索引或其他操作，大大提高了可读性、易用性，防止出错。

```
1 # 在PyTorch 1.3之前，需要使用注释
2 # Tensor[N, C, H, W]
3 images = torch.randn(32, 3, 56, 56)
4 images.sum(dim=1)
5 images.select(dim=1, index=0)
6
7 # PyTorch 1.3之后
8 NCHW = ['N', 'C', 'H', 'W']
9 images = torch.randn(32, 3, 56, 56, names=NCHW)
10 images.sum('C')
11 images.select('C', index=0)
12 # 也可以这么设置
13 tensor = torch.rand(3,4,1,2,names=('C', 'N', 'H', 'W'))
14 # 使用align_to可以对维度方便地排序
15 tensor = tensor.align_to('N', 'C', 'H', 'W')
```

数据类型转换

```
1 # 设置默认类型，pytorch中的FloatTensor远远快于DoubleTensor
2 torch.set_default_tensor_type(torch.FloatTensor)
3
```

```
4 # 类型转换
5 tensor = tensor.cuda()
6 tensor = tensor.cpu()
7 tensor = tensor.float()
8 tensor = tensor.long()
```

torch.Tensor与np.ndarray转换

除了CharTensor，其他所有CPU上的张量都支持转换为numpy格式然后再转换回来。

```
1 ndarray = tensor.cpu().numpy()
2 tensor = torch.from_numpy(ndarray).float()
3 tensor = torch.from_numpy(ndarray.copy()).float() # If ndarray has
negative stride.
```

Torch.tensor与PIL.Image转换

```
1 # pytorch中的张量默认采用[N, C, H, W]的顺序，并且数据范围在[0,1]，需要进行转置
2 和规范化
3 # torch.Tensor -> PIL.Image
4 image = PIL.Image.fromarray(torch.clamp(tensor*255, min=0,
5 max=255).byte().permute(1,2,0).cpu().numpy())
6 image = torchvision.transforms.functional.to_pil_image(tensor) #
7 Equivalently way
8
```

```
9 # PIL.Image -> torch.Tensor
  path = r'./figure.jpg'
  tensor =
  torch.from_numpy(np.asarray(PIL.Image.open(path))).permute(2,0,1).float(
  / 255
  tensor =
  torchvision.transforms.functional.to_tensor(PIL.Image.open(path)) #
  Equivalently way
```

np.ndarray与PIL.Image的转换

```
1 image = PIL.Image.fromarray(ndarray.astype(np.uint8))
2
3 ndarray = np.asarray(PIL.Image.open(path))
```

从只包含一个元素的张量中提取值

```
1 value = torch.rand(1).item()
```

张量形变

```
1 # 在将卷积层输入全连接层的情况下通常需要对张量做形变处理，
2 # 相比torch.view, torch.reshape可以自动处理输入张量不连续的情况。
3 tensor = torch.rand(2,3,4)
```

```
4 shape = (6, 4)
5 tensor = torch.reshape(tensor, shape)
```

打乱顺序

```
1 tensor = tensor[torch.randperm(tensor.size(0))] # 打乱第一个维度
```

水平翻转

```
1 # pytorch不支持tensor[::-1]这样的负步长操作，水平翻转可以通过张量索引实现
2 # 假设张量的维度为[N, D, H, W].
3 tensor = tensor[:, :, :, torch.arange(tensor.size(3) - 1, -1,
    -1).long()]
```

复制张量

1	# Operation			New/Shared memory		Still in
2	computation graph					
3	tensor.clone()	#		New		Yes
4						
	tensor.detach()	#		Shared		No
	tensor.detach.clone()()	#		New		No

张量拼接

```
1 '''
2 注意torch.cat和torch.stack的区别在于torch.cat沿着给定的维度拼接，
3 而torch.stack会新增一维。例如当参数是3个10x5的张量，torch.cat的结果是30x5的张
4 量，
5 而torch.stack的结果是3x10x5的张量。
6 '''
7 tensor = torch.cat(list_of_tensors, dim=0)
   tensor = torch.stack(list_of_tensors, dim=0)
```

将整数标签转为one-hot编码

```
1 # pytorch的标记默认从0开始
2 tensor = torch.tensor([0, 2, 1, 3])
3 N = tensor.size(0)
4 num_classes = 4
5 one_hot = torch.zeros(N, num_classes).long()
6 one_hot.scatter_(dim=1, index=torch.unsqueeze(tensor, dim=1),
   src=torch.ones(N, num_classes).long())
```

得到非零元素

```
1 torch.nonzero(tensor)           # index of non-zero elements
2 torch.nonzero(tensor==0)        # index of zero elements
```

```
3 torch.nonzero(tensor).size(0)      # number of non-zero elements
4 torch.nonzero(tensor == 0).size(0) # number of zero elements
```

判断两个张量相等

```
1 torch.allclose(tensor1, tensor2) # float tensor
2 torch.equal(tensor1, tensor2)    # int tensor
```

张量扩展

```
1 # Expand tensor of shape 64*512 to shape 64*512*7*7.
2 tensor = torch.rand(64,512)
3 torch.reshape(tensor, (64, 512, 1, 1)).expand(64, 512, 7, 7)
```

矩阵乘法

```
1 # Matrix multiplication: (m*n) * (n*p) * -> (m*p).
2 result = torch.mm(tensor1, tensor2)
3
4 # Batch matrix multiplication: (b*m*n) * (b*n*p) -> (b*m*p)
5 result = torch.bmm(tensor1, tensor2)
6
7 # Element-wise multiplication.
8 result = tensor1 * tensor2
```

计算两组数据之间的两两欧式距离

利用broadcast机制

```
1 dist = torch.sqrt(torch.sum((X1[:,None,:] - X2) ** 2, dim=2))
```

3. 模型定义和操作

一个简单两层卷积网络的示例

```
1 # convolutional neural network (2 convolutional layers)
2 class ConvNet(nn.Module):
3     def __init__(self, num_classes=10):
4         super(ConvNet, self).__init__()
5         self.layer1 = nn.Sequential(
6             nn.Conv2d(1, 16, kernel_size=5, stride=1, padding=2),
7             nn.BatchNorm2d(16),
8             nn.ReLU(),
9             nn.MaxPool2d(kernel_size=2, stride=2))
10        self.layer2 = nn.Sequential(
11            nn.Conv2d(16, 32, kernel_size=5, stride=1, padding=2),
12            nn.BatchNorm2d(32),
13            nn.ReLU(),
14            nn.MaxPool2d(kernel_size=2, stride=2))
15        self.fc = nn.Linear(7*7*32, num_classes)
16
```

```

17     def forward(self, x):
18         out = self.layer1(x)
19         out = self.layer2(out)
20         out = out.reshape(out.size(0), -1)
21         out = self.fc(out)
22         return out
23
24
25 model = ConvNet(num_classes).to(device)

```

卷积层的计算和展示可以用这个网站辅助。

双线性汇合 (bilinear pooling)

```

1 X = torch.reshape(N, D, H * W) # Assume X has
2 shape N*D*H*W
3 X = torch.bmm(X, torch.transpose(X, 1, 2)) / (H * W) # Bilinear
4 pooling
5 assert X.size() == (N, D, D)
6 X = torch.reshape(X, (N, D * D))
  X = torch.sign(X) * torch.sqrt(torch.abs(X) + 1e-5) # Signed-sqrt
  normalization
  X = torch.nn.functional.normalize(X) # L2
  normalization

```

多卡同步 BN (Batch normalization)

当使用 `torch.nn.DataParallel` 将代码运行在多张 GPU 卡上时，PyTorch 的 BN 层默认操作是各卡上数据独立地计算均值和标准差，同步 BN 使用所有卡上的数据一起计算 BN 层的均值和标准差，缓解了当批量大小（batch size）比较小时对均值和标准差估计不准的情况，是在目标检测等任务中一个有效的提升性能的技巧。

```
1 sync_bn = torch.nn.SyncBatchNorm(num_features, eps=1e-05,  
2 momentum=0.1, affine=True,  
                                     track_running_stats=True)
```

将已有网络的所有BN层改为同步BN层

```
1 def convertBNtoSyncBN(module, process_group=None):  
2     '''Recursively replace all BN layers to SyncBN layer.  
3  
4     Args:  
5         module[torch.nn.Module]. Network  
6     '''  
7     if isinstance(module, torch.nn.modules.batchnorm._BatchNorm):  
8         sync_bn = torch.nn.SyncBatchNorm(module.num_features,  
9 module.eps, module.momentum,  
10                                     module.affine,  
11 module.track_running_stats, process_group)  
12         sync_bn.running_mean = module.running_mean  
13         sync_bn.running_var = module.running_var
```

```

14         if module.affine:
15             sync_bn.weight = module.weight.clone().detach()
16             sync_bn.bias = module.bias.clone().detach()
17         return sync_bn
18     else:
19         for name, child_module in module.named_children():
20             setattr(module, name) =
convert_syncbn_model(child_module, process_group=process_group))
21         return module

```

类似 BN 滑动平均

如果实现类似 BN 滑动平均的操作，在 forward 函数中要使用原地（inplace）操作给滑动平均赋值。

```

1 class BN(torch.nn.Module)
2     def __init__(self):
3         ...
4         self.register_buffer('running_mean',
5 torch.zeros(num_features))
6
7     def forward(self, X):
8         ...
9         self.running_mean += momentum * (current - self.running_mean)

```

计算模型整体参数量

```
1 num_parameters = sum(torch.numel(parameter) for parameter in
    model.parameters())
```

查看网络中的参数

可以通过`model.state_dict()`或者`model.named_parameters()`函数查看现在的全部可训练参数（包括通过继承得到的父类中的参数）

```
1 params = list(model.named_parameters())
2 (name, param) = params[28]
3 print(name)
4 print(param.grad)
5 print('-----')
6 (name2, param2) = params[29]
7 print(name2)
8 print(param2.grad)
9 print('-----')
10 (name1, param1) = params[30]
11 print(name1)
12 print(param1.grad)
```

模型可视化（使用pytorchviz）

szagoruyko/pytorchvizgithub.com

类似 Keras 的 `model.summary()` 输出模型信息，使用 `pytorch-summary`

sksq96/pytorch-summarygithub.com

模型权重初始化

注意 `model.modules()` 和 `model.children()` 的区别：`model.modules()` 会迭代地遍历模型的所有子层，而 `model.children()` 只会遍历模型下的一层。

```
1 # Common practise for initialization.
2 for layer in model.modules():
3     if isinstance(layer, torch.nn.Conv2d):
4         torch.nn.init.kaiming_normal_(layer.weight, mode='fan_out',
5                                         nonlinearity='relu')
6         if layer.bias is not None:
7             torch.nn.init.constant_(layer.bias, val=0.0)
8     elif isinstance(layer, torch.nn.BatchNorm2d):
9         torch.nn.init.constant_(layer.weight, val=1.0)
10        torch.nn.init.constant_(layer.bias, val=0.0)
11    elif isinstance(layer, torch.nn.Linear):
12        torch.nn.init.xavier_normal_(layer.weight)
13        if layer.bias is not None:
14            torch.nn.init.constant_(layer.bias, val=0.0)
15
```

```
16 # Initialization with given tensor.
17 layer.weight = torch.nn.Parameter(tensor)
```

提取模型中的某一层

`modules()`会返回模型中所有模块的迭代器，它能够访问到最内层，比如`self.layer1.conv1`这个模块，还有一个与它们相对应的是`name_children()`属性以及`named_modules()`，这两个不仅会返回模块的迭代器，还会返回网络层的名字。

```
1 # 取模型中的前两层
2 new_model = nn.Sequential(*list(model.children())[ :2])
3 # 如果希望提取出模型中的所有卷积层，可以像下面这样操作：
4 for layer in model.named_modules():
5     if isinstance(layer[1], nn.Conv2d):
6         conv_model.add_module(layer[0], layer[1])
```

部分层使用预训练模型

注意如果保存的模型是 `torch.nn.DataParallel`，则当前的模型也需要是

```
1 model.load_state_dict(torch.load('model.pth'), strict=False)
```

将在 GPU 保存的模型加载到 CPU

```
1 model.load_state_dict(torch.load('model.pth', map_location='cpu'))
```

导入另一个模型的相同部分到新的模型

模型导入参数时，如果两个模型结构不一致，则直接导入参数会报错。用下面方法可以把另一个模型的相同的部分导入到新的模型中。

```
1 # model_new代表新的模型
2 # model_saved代表其他模型，比如用torch.load导入的已保存的模型
3 model_new_dict = model_new.state_dict()
4 model_common_dict = {k:v for k, v in model_saved.items() if k in
5 model_new_dict.keys()}
6 model_new_dict.update(model_common_dict)
   model_new.load_state_dict(model_new_dict)
```

4. 数据处理

计算数据集的均值和标准差

```
1 import os
2 import cv2
3 import numpy as np
4 from torch.utils.data import Dataset
5 from PIL import Image
6
7
```

```
8 def compute_mean_and_std(dataset):
9     # 输入PyTorch的dataset，输出均值和标准差
10    mean_r = 0
11    mean_g = 0
12    mean_b = 0
13
14    for img, _ in dataset:
15        img = np.asarray(img) # change PIL Image to numpy array
16        mean_b += np.mean(img[:, :, 0])
17        mean_g += np.mean(img[:, :, 1])
18        mean_r += np.mean(img[:, :, 2])
19
20    mean_b /= len(dataset)
21    mean_g /= len(dataset)
22    mean_r /= len(dataset)
23
24    diff_r = 0
25    diff_g = 0
26    diff_b = 0
27
28    N = 0
29
30    for img, _ in dataset:
31        img = np.asarray(img)
32
33        diff_b += np.sum(np.power(img[:, :, 0] - mean_b, 2))
34        diff_g += np.sum(np.power(img[:, :, 1] - mean_g, 2))
```

```

35         diff_r += np.sum(np.power(img[:, :, 2] - mean_r, 2))
36
37         N += np.prod(img[:, :, 0].shape)
38
39     std_b = np.sqrt(diff_b / N)
40     std_g = np.sqrt(diff_g / N)
41     std_r = np.sqrt(diff_r / N)
42
43     mean = (mean_b.item() / 255.0, mean_g.item() / 255.0,
44 mean_r.item() / 255.0)
45     std = (std_b.item() / 255.0, std_g.item() / 255.0, std_r.item()
46 / 255.0)
47     return mean, std

```

得到视频数据基本信息

```

1  import cv2
2  video = cv2.VideoCapture(mp4_path)
3  height = int(video.get(cv2.CAP_PROP_FRAME_HEIGHT))
4  width = int(video.get(cv2.CAP_PROP_FRAME_WIDTH))
5  num_frames = int(video.get(cv2.CAP_PROP_FRAME_COUNT))
6  fps = int(video.get(cv2.CAP_PROP_FPS))
7  video.release()

```

TSN 每段 (segment) 采样一帧视频

```

1 K = self._num_segments
2 if is_train:
3     if num_frames > K:
4         # Random index for each segment.
5         frame_indices = torch.randint(
6             high=num_frames // K, size=(K,), dtype=torch.long)
7         frame_indices += num_frames // K * torch.arange(K)
8     else:
9         frame_indices = torch.randint(
10            high=num_frames, size=(K - num_frames,),
11            dtype=torch.long)
12         frame_indices = torch.sort(torch.cat((
13             torch.arange(num_frames), frame_indices)))[0]
14 else:
15     if num_frames > K:
16         # Middle index for each segment.
17         frame_indices = num_frames / K // 2
18         frame_indices += num_frames // K * torch.arange(K)
19     else:
20         frame_indices = torch.sort(torch.cat((
21             torch.arange(num_frames), torch.arange(K -
22 num_frames)))[0]
23         assert frame_indices.size() == (K,)
24         return [frame_indices[i] for i in range(K)]

```

常用训练和验证数据预处理

其中 ToTensor 操作会将 PIL.Image 或形状为 H×W×D，数值范围为 [0, 255] 的 np.ndarray 转换为形状为 D×H×W，数值范围为 [0.0, 1.0] 的 torch.Tensor。

```
1 train_transform = torchvision.transforms.Compose([
2     torchvision.transforms.RandomResizedCrop(size=224,
3                                             scale=(0.08, 1.0)),
4     torchvision.transforms.RandomHorizontalFlip(),
5     torchvision.transforms.ToTensor(),
6     torchvision.transforms.Normalize(mean=(0.485, 0.456, 0.406),
7                                         std=(0.229, 0.224, 0.225)),
8 ])
9 val_transform = torchvision.transforms.Compose([
10    torchvision.transforms.Resize(256),
11    torchvision.transforms.CenterCrop(224),
12    torchvision.transforms.ToTensor(),
13    torchvision.transforms.Normalize(mean=(0.485, 0.456, 0.406),
14                                     std=(0.229, 0.224, 0.225)),
15 ])
```

5. 模型训练和测试

分类模型训练代码

```
1 # Loss and optimizer
2 criterion = nn.CrossEntropyLoss()
```

```

3 optimizer = torch.optim.Adam(model.parameters(), lr=learning_rate)
4
5 # Train the model
6 total_step = len(train_loader)
7 for epoch in range(num_epochs):
8     for i ,(images, labels) in enumerate(train_loader):
9         images = images.to(device)
10        labels = labels.to(device)
11
12        # Forward pass
13        outputs = model(images)
14        loss = criterion(outputs, labels)
15
16        # Backward and optimizer
17        optimizer.zero_grad()
18        loss.backward()
19        optimizer.step()
20
21        if (i+1) % 100 == 0:
22            print('Epoch: [{}/{}], Step: [{}/{}], Loss: {}'.format(
23                epoch+1, num_epochs, i+1, total_step,
24                loss.item()))

```

分类模型测试代码

```

1 # Test the model

```

```

2 model.eval() # eval mode(batch norm uses moving mean/variance
3               #instead of mini-batch mean/variance)
4 with torch.no_grad():
5     correct = 0
6     total = 0
7     for images, labels in test_loader:
8         images = images.to(device)
9         labels = labels.to(device)
10        outputs = model(images)
11        _, predicted = torch.max(outputs.data, 1)
12        total += labels.size(0)
13        correct += (predicted == labels).sum().item()
14
15    print('Test accuracy of the model on the 10000 test images: {}'.
16          %'
          .format(100 * correct / total))

```

自定义loss

继承torch.nn.Module类写自己的loss。

```

1 class MyLoss(torch.nn.Moudle):
2     def __init__(self):
3         super(MyLoss, self).__init__()
4
5     def forward(self, x, y):

```

```
6         loss = torch.mean((x - y) ** 2)
7         return loss
```

标签平滑 (label smoothing)

写一个label_smoothing.py的文件，然后在训练代码里引用，用LSR代替交叉熵损失即可。label_smoothing.py内容如下：

```
1  import torch
2  import torch.nn as nn
3
4
5  class LSR(nn.Module):
6
7      def __init__(self, e=0.1, reduction='mean'):
8          super().__init__()
9
10         self.log_softmax = nn.LogSoftmax(dim=1)
11         self.e = e
12         self.reduction = reduction
13
14     def _one_hot(self, labels, classes, value=1):
15         """
16         Convert labels to one hot vectors
17
18         Args:
```

```

19         labels: torch tensor in format [label1, label2, label3,
20 ...]
21         classes: int, number of classes
22         value: label value in one hot vector, default to 1
23
24     Returns:
25         return one hot format labels in shape [batchsize,
26 classes]
27     """
28
29     one_hot = torch.zeros(labels.size(0), classes)
30
31     #labels and value_added size must match
32     labels = labels.view(labels.size(0), -1)
33     value_added = torch.Tensor(labels.size(0), 1).fill_(value)
34
35     value_added = value_added.to(labels.device)
36     one_hot = one_hot.to(labels.device)
37
38     one_hot.scatter_add_(1, labels, value_added)
39
40     return one_hot
41
42     def _smooth_label(self, target, length, smooth_factor):
43         """convert targets to one-hot format, and smooth
44         them.
45         Args:

```

```

46         target: target in form with [label1, label2,
47 label_batchsize]
48         length: length of one-hot format(number of classes)
49         smooth_factor: smooth factor for label smooth
50
51     Returns:
52         smoothed labels in one hot format
53     """
54     one_hot = self._one_hot(target, length, value=1 -
55 smooth_factor)
56     one_hot += smooth_factor / (length - 1)
57
58     return one_hot.to(target.device)
59
60     def forward(self, x, target):
61
62         if x.size(0) != target.size(0):
63             raise ValueError('Expected input batchsize ({{}}) to match
64 target batch_size({})'
65                               .format(x.size(0), target.size(0)))
66
67         if x.dim() < 2:
68             raise ValueError('Expected input tensor to have least 2
69 dimensions(got {{}})'
70                               .format(x.size(0)))
71
72         if x.dim() != 2:

```

```

73         raise ValueError('Only 2 dimension tensor are
74 implemented, (got {})'
75         .format(x.size()))
76
77
78         smoothed_target = self._smooth_label(target, x.size(1),
79 self.e)
80         x = self.log_softmax(x)
81         loss = torch.sum(- x * smoothed_target, dim=1)
82
83         if self.reduction == 'none':
84             return loss
85
86         elif self.reduction == 'sum':
87             return torch.sum(loss)
88
89         elif self.reduction == 'mean':
90             return torch.mean(loss)
91
92         else:
93             raise ValueError('unrecognized option, expect reduction
to be one of none, mean, sum')

```

或者直接在训练文件里做label smoothing

```

1 for images, labels in train_loader:

```

```

2     images, labels = images.cuda(), labels.cuda()
3     N = labels.size(0)
4     # C is the number of classes.
5     smoothed_labels = torch.full(size=(N, C), fill_value=0.1 / (C -
6 1)).cuda()
7     smoothed_labels.scatter_(dim=1, index=torch.unsqueeze(labels,
8 dim=1), value=0.9)
9
10    score = model(images)
11    log_prob = torch.nn.functional.log_softmax(score, dim=1)
12    loss = -torch.sum(log_prob * smoothed_labels) / N
13    optimizer.zero_grad()
14    loss.backward()
15    optimizer.step()

```

Mixup训练

```

1  beta_distribution = torch.distributions.beta.Beta(alpha, alpha)
2  for images, labels in train_loader:
3      images, labels = images.cuda(), labels.cuda()
4
5      # Mixup images and labels.
6      lambda_ = beta_distribution.sample([]).item()
7      index = torch.randperm(images.size(0)).cuda()
8      mixed_images = lambda_ * images + (1 - lambda_) * images[index,
9 :]

```

```

10     label_a, label_b = labels, labels[index]
11
12     # Mixup loss.
13     scores = model(mixed_images)
14     loss = (lambda_ * loss_function(scores, label_a)
15           + (1 - lambda_) * loss_function(scores, label_b))
16     optimizer.zero_grad()
17     loss.backward()
18     optimizer.step()

```

L1 正则化

```

1  l1_regularization = torch.nn.L1Loss(reduction='sum')
2  loss = ... # Standard cross-entropy loss
3  for param in model.parameters():
4      loss += torch.sum(torch.abs(param))
5  loss.backward()

```

不对偏置项进行权重衰减 (weight decay)

pytorch里的weight decay相当于l2正则

```

1  bias_list = (param for name, param in model.named_parameters() if
2  name[-4:] == 'bias')
3  others_list = (param for name, param in model.named_parameters() if

```

```
4 name[-4:] != 'bias')
5 parameters = [{'parameters': bias_list, 'weight_decay': 0},
                 {'parameters': others_list}]
optimizer = torch.optim.SGD(parameters, lr=1e-2, momentum=0.9,
                             weight_decay=1e-4)
```

梯度裁剪 (gradient clipping)

```
1 torch.nn.utils.clip_grad_norm_(model.parameters(), max_norm=20)
```

得到当前学习率

```
1 # If there is one global learning rate (which is the common case).
2 lr = next(iter(optimizer.param_groups))['lr']
3
4 # If there are multiple learning rates for different layers.
5 all_lr = []
6 for param_group in optimizer.param_groups:
7     all_lr.append(param_group['lr'])
```

另一种方法，在一个batch训练代码里，当前的lr是`optimizer.param_groups[0]['lr']`

学习率衰减

```
1 # Reduce learning rate when validation accuracy plateau.
2 scheduler = torch.optim.lr_scheduler.ReduceLROnPlateau(optimizer,
3 mode='max', patience=5, verbose=True)
4 for t in range(0, 80):
5     train(...)
6     val(...)
7     scheduler.step(val_acc)
8
9 # Cosine annealing learning rate.
10 scheduler = torch.optim.lr_scheduler.CosineAnnealingLR(optimizer,
11 T_max=80)
12 # Reduce learning rate by 10 at given epochs.
13 scheduler = torch.optim.lr_scheduler.MultiStepLR(optimizer,
14 milestones=[50, 70], gamma=0.1)
15 for t in range(0, 80):
16     scheduler.step()
17     train(...)
18     val(...)
19
20 # Learning rate warmup by 10 epochs.
21 scheduler = torch.optim.lr_scheduler.LambdaLR(optimizer,
22 lr_lambda=lambda t: t / 10)
23 for t in range(0, 10):
24     scheduler.step()
25     train(...)
26     val(...)
```

优化器链式更新

从1.4版本开始，torch.optim.lr_scheduler 支持链式更新（chaining），即用户可以定义两个 schedulers，并交替在训练中使用。

```
1 import torch
2 from torch.optim import SGD
3 from torch.optim.lr_scheduler import ExponentialLR, StepLR
4 model = [torch.nn.Parameter(torch.randn(2, 2, requires_grad=True))]
5 optimizer = SGD(model, 0.1)
6 scheduler1 = ExponentialLR(optimizer, gamma=0.9)
7 scheduler2 = StepLR(optimizer, step_size=3, gamma=0.1)
8 for epoch in range(4):
9     print(epoch, scheduler2.get_last_lr()[0])
10    optimizer.step()
11    scheduler1.step()
12    scheduler2.step()
```

模型训练可视化

PyTorch可以使用tensorboard来可视化训练过程。

安装和运行TensorBoard。

```
1 pip install tensorboard
2 tensorboard --logdir=runs
```

使用SummaryWriter类来收集和可视化相应的数据，为了方便查看，可以使用不同的文件夹，比如'Loss/train'和'Loss/test'。

```
1 from torch.utils.tensorboard import SummaryWriter
2 import numpy as np
3
4 writer = SummaryWriter()
5
6 for n_iter in range(100):
7     writer.add_scalar('Loss/train', np.random.random(), n_iter)
8     writer.add_scalar('Loss/test', np.random.random(), n_iter)
9     writer.add_scalar('Accuracy/train', np.random.random(), n_iter)
10    writer.add_scalar('Accuracy/test', np.random.random(), n_iter)
```

保存与加载断点

注意为了能够恢复训练，我们需要同时保存模型和优化器的状态，以及当前的训练轮数。

```
1 start_epoch = 0
2 # Load checkpoint.
3 if resume: # resume为参数，第一次训练时设为0，中断再训练时设为1
4     model_path = os.path.join('model', 'best_checkpoint.pth.tar')
5     assert os.path.isfile(model_path)
6     checkpoint = torch.load(model_path)
7     best_acc = checkpoint['best_acc']
```

```
8     start_epoch = checkpoint['epoch']
9     model.load_state_dict(checkpoint['model'])
10    optimizer.load_state_dict(checkpoint['optimizer'])
11    print('Load checkpoint at epoch {}'.format(start_epoch))
12    print('Best accuracy so far {}'.format(best_acc))
13
14    # Train the model
15    for epoch in range(start_epoch, num_epochs):
16        ...
17
18        # Test the model
19        ...
20
21        # save checkpoint
22        is_best = current_acc > best_acc
23        best_acc = max(current_acc, best_acc)
24        checkpoint = {
25            'best_acc': best_acc,
26            'epoch': epoch + 1,
27            'model': model.state_dict(),
28            'optimizer': optimizer.state_dict(),
29        }
30        model_path = os.path.join('model', 'checkpoint.pth.tar')
31        best_model_path = os.path.join('model',
32 'best_checkpoint.pth.tar')
33        torch.save(checkpoint, model_path)
34        if is_best:
```

```
shutil.copy(model_path, best_model_path)
```

提取 ImageNet 预训练模型某层的卷积特征

```
1 # VGG-16 relu5-3 feature.
2 model = torchvision.models.vgg16(pretrained=True).features[:-1]
3 # VGG-16 pool5 feature.
4 model = torchvision.models.vgg16(pretrained=True).features
5 # VGG-16 fc7 feature.
6 model = torchvision.models.vgg16(pretrained=True)
7 model.classifier =
8 torch.nn.Sequential(*list(model.classifier.children())[:-3])
9 # ResNet GAP feature.
10 model = torchvision.models.resnet18(pretrained=True)
11 model = torch.nn.Sequential(collections.OrderedDict(
12     list(model.named_children())[:-1]))
13
14 with torch.no_grad():
15     model.eval()
16     conv_representation = model(image)
```

提取 ImageNet 预训练模型多层的卷积特征

```
1 class FeatureExtractor(torch.nn.Module):
2     """Helper class to extract several convolution features from the
```

```

3 given
4     pre-trained model.
5
6     Attributes:
7         _model, torch.nn.Module.
8         _layers_to_extract, list<str> or set<str>
9
10    Example:
11        >>> model = torchvision.models.resnet152(pretrained=True)
12        >>> model = torch.nn.Sequential(collections.OrderedDict(
13            list(model.named_children())[:-1]))
14        >>> conv_representation = FeatureExtractor(
15            pretrained_model=model,
16            layers_to_extract={'layer1', 'layer2', 'layer3',
17 'layer4'})(image)
18    """
19    def __init__(self, pretrained_model, layers_to_extract):
20        torch.nn.Module.__init__(self)
21        self._model = pretrained_model
22        self._model.eval()
23        self._layers_to_extract = set(layers_to_extract)
24
25    def forward(self, x):
26        with torch.no_grad():
27            conv_representation = []
28            for name, layer in self._model.named_children():
29                x = layer(x)

```

```
30         if name in self._layers_to_extract:
31             conv_representation.append(x)
32     return conv_representation
```

微调全连接层

```
1 model = torchvision.models.resnet18(pretrained=True)
2 for param in model.parameters():
3     param.requires_grad = False
4 model.fc = nn.Linear(512, 100) # Replace the last fc layer
5 optimizer = torch.optim.SGD(model.fc.parameters(), lr=1e-2,
6                               momentum=0.9, weight_decay=1e-4)
```

以较大学习率微调全连接层，较小学习率微调卷积层

```
1 model = torchvision.models.resnet18(pretrained=True)
2 finetuned_parameters = list(map(id, model.fc.parameters()))
3 conv_parameters = (p for p in model.parameters() if id(p) not in
4 finetuned_parameters)
5 parameters = [{'params': conv_parameters, 'lr': 1e-3},
6               {'params': model.fc.parameters()}]
7 optimizer = torch.optim.SGD(parameters, lr=1e-2, momentum=0.9,
8                               weight_decay=1e-4)
```

6. 其他注意事项

不要使用太大的线性层。因为`nn.Linear(m,n)`使用的是 $O(mn)$ 的内存，线性层太大很容易超出现有显存。

不要在太长的序列上使用RNN。因为RNN反向传播使用的是BPTT算法，其需要的内存和输入序列的长度呈线性关系。

`model(x)` 前用 `model.train()` 和 `model.eval()` 切换网络状态。

不需要计算梯度的代码块用 `with torch.no_grad()` 包含起来。

`model.eval()` 和 `torch.no_grad()` 的区别在于，`model.eval()` 是将网络切换为测试状态，例如 BN 和 dropout 在训练和测试阶段使用不同的计算方法。`torch.no_grad()` 是关闭 PyTorch 张量的自动求导机制，以减少存储使用和加速计算，得到的结果无法进行 `loss.backward()`。

`model.zero_grad()` 会把整个模型的参数的梯度都归零，而 `optimizer.zero_grad()` 只会把传入其中的参数的梯度归零。

`torch.nn.CrossEntropyLoss` 的输入不需要经过 Softmax。`torch.nn.CrossEntropyLoss` 等价于 `torch.nn.functional.log_softmax + torch.nn.NLLLoss`。

`loss.backward()` 前用 `optimizer.zero_grad()` 清除累积梯度。

`torch.utils.data.DataLoader` 中尽量设置 `pin_memory=True`，对特别小的数据集如 MNIST 设置 `pin_memory=False` 反而更快一些。`num_workers` 的设置需要在实验中找到最快的取值。

用 `del` 及时删除不用的中间变量，节约 GPU 存储。

使用 inplace 操作可节约 GPU 存储，如

```
1 x = torch.nn.functional.relu(x, inplace=True)
```

减少 CPU 和 GPU 之间的数据传输。例如如果你想知道一个 epoch 中每个 mini-batch 的 loss 和准确率，先将它们累积在 GPU 中等一个 epoch 结束之后一起传输回 CPU 会比每个 mini-batch

h 都进行一次 GPU 到 CPU 的传输更快。

使用半精度浮点数 `half()` 会有一定的速度提升，具体效率依赖于 GPU 型号。需要小心数值精度过低带来的稳定性问题。

时常使用 `assert tensor.size() == (N, D, H, W)` 作为调试手段，确保张量维度和你设想中一致。

除了标记 `y` 外，尽量少使用一维张量，使用 `n*1` 的二维张量代替，可以避免一些意想不到的一维张量计算结果。

统计代码各部分耗时

```
1 with torch.autograd.profiler.profile(enabled=True, use_cuda=False) as
  profile:    ...print(profile)# 或者在命令行运行python -m
            torch.utils.bottleneck main.py
```

使用TorchSnooper来调试PyTorch代码，程序在执行的时候，就会自动 `print` 出来每一行的执行结果的 `tensor` 的形状、数据类型、设备、是否需要梯度的信息。

```
1 # pip install torchsnooperimport torchsnooper# 对于函数，使用修饰器
  @torchsnooper.snoop()# 如果不是函数，使用 with 语句来激活 TorchSnooper，把训
    练的那个循环装进 with 语句中去。with torchsnooper.snoop():    原本的代码
```

<https://github.com/zasdfgbnm/TorchSnooper>github.com

模型可解释性，使用captum库：<https://captum.ai/captum.ai>
